Final Project Demo
School of Engineering Science
Simon Fraser University

Roadmap

- Project Description
- Modified MobileNode in ns-2
- AODV Routing in ns-2
- Modified AODV with Interface Switching Capability
- Simulation
 - Configuration
 - Interface Switching
 - Sample ns-2 Output
 - Average Throughputs
 - Observations

Project Description

- Extend the Network Simulator (ns-2.32) to support multiple channels and multiple interfaces by referring to [1]
 - modify ns-2's MobileNode library to support multiple interfaces
 - preserve the legacy operations of IEEE 802.11 interfaces
- Implement the **interface switching** protocol proposed in [2]
 - integrate this algorithm in the existing AODV routing agent in ns-2
- Simulate a multi-channel multi-interface ad-hoc wireless network (in **chain topologies**) using the modified ns-2
 - demonstrate the **effectiveness of interface switching** and the **improvement in the network throughput**

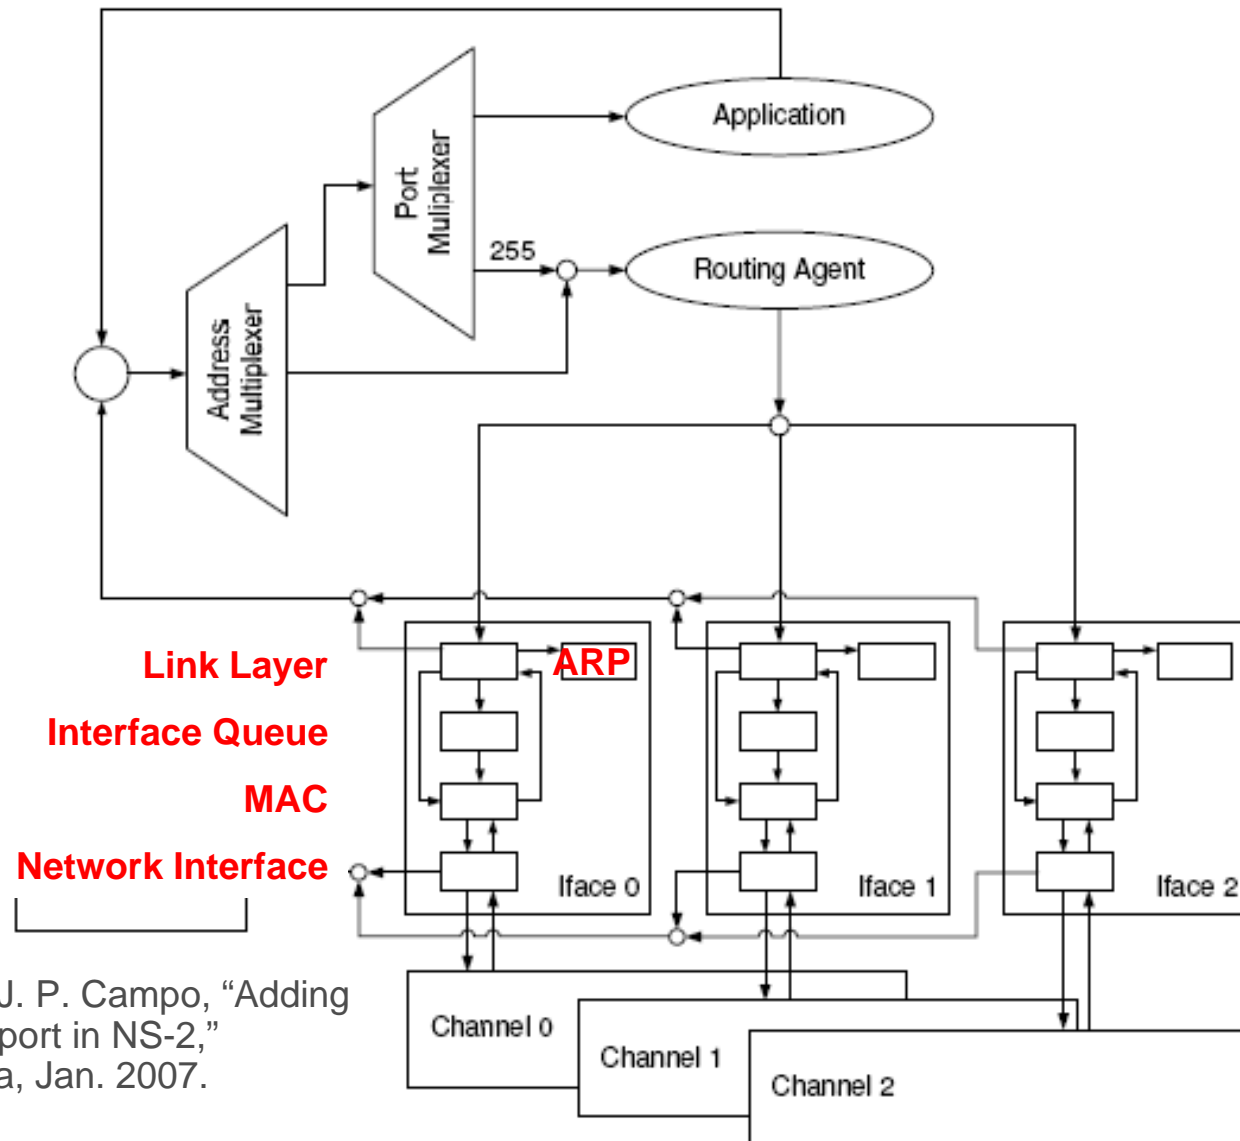

AODV Ad-hoc On-demand Distance Vector

Modified MobileNode in ns-2

- Each node can have as many instances of the link layer, ARP, interface queue, MAC, network interface and channel entities as the number of interfaces

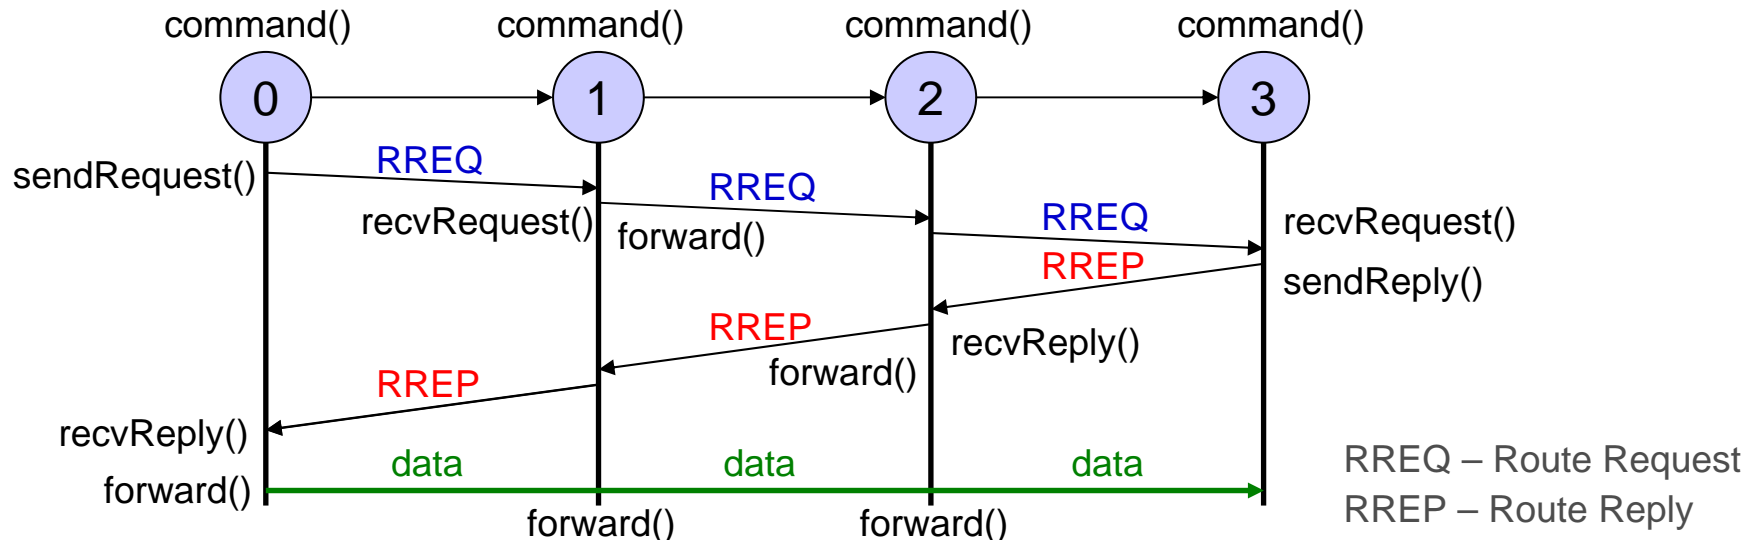

From: [1] R. A. Calvo and J. P. Campo, "Adding Multiple Interface Support in NS-2," University of Cantabria, Jan. 2007.

AODV Routing in ns-2

- Route establishment:

- source node broadcasts a RREQ to find a route to destination node
- each node receiving the RREQ forwards to the next node
- a route is determined when the RREQ reaches a node that offers accessibility to destination node
- the route is established by sending a RREP back to source node

Modified AODV with Interface Switching Capability

- **command()**
 - initially, the node chooses a random channel for its fixed interface and switchable interface
 - add the fixed channel used by this node to its **NeighbourTable**
 - update the node's **ChannelUsageList** with its fixed channel
- **sendRequest(), sendReply(), sendHello()**
 - add the fixed channel used by this node and its **NeighbourTable** to the outgoing **RREQ**, **RREP**, or **Hello** packet
- **recvRequest(), recvReply(), recvHello()**
 - when the node receives a **RREQ**, **RREP**, or **Hello** packet from a neighbour, it updates:
 - the node's **NeighbourTable** with the fixed channel of that neighbour
 - the node's **ChannelUsageList** using the **NeighbourTable** of its neighbour.

Modified AODV with Interface Switching Capability

- **forward()**

- RREQ or RREP:

- add the fixed channel used by this node and its **NeighbourTable** to the outgoing packet

- data:

- consult the node's **ChannelUsageList**, find the channel with the largest usage
- if the node's fixed channel has the largest usage:
 - with a probability of 0.4 (from paper [2]), the node:
 - reverses its **ChannelUsageList** about the fixed channel previously used
 - changes its fixed channel to a less used channel
 - transmits a new **Hello** packet informing neighbours of its new fixed channel → **sendHello()**
- if the usage of the node's fixed channel is ok:
 - look up the fixed channel of the next node in **NeighbourTable**
 - assign this fixed channel to the node's **switchable interface**

Simulation: Configuration

- Using the modified ns-2.32:
 - test the effectiveness of **interface switching** and **throughput** in multi-channel and multi-interface ad-hoc wireless networks

- Scenarios:
 - simple chain topologies of **2-11 stationary nodes** (single route)
 - **2-4 channels per node**
 - **2 interfaces per node** (1 fixed, 1 switchable)
 - simulation duration: **60 s** (actual simulation time is slightly longer)
 - channel capacity: **5.4 Mbps**
 - **constant bit-rate (CBR) traffic** flow from Node 0 to Node N-1
 - transmitted over **UDP** (no flow and congestion controls)
 - **1000 bytes** per packet, sent every **1.4 ms**

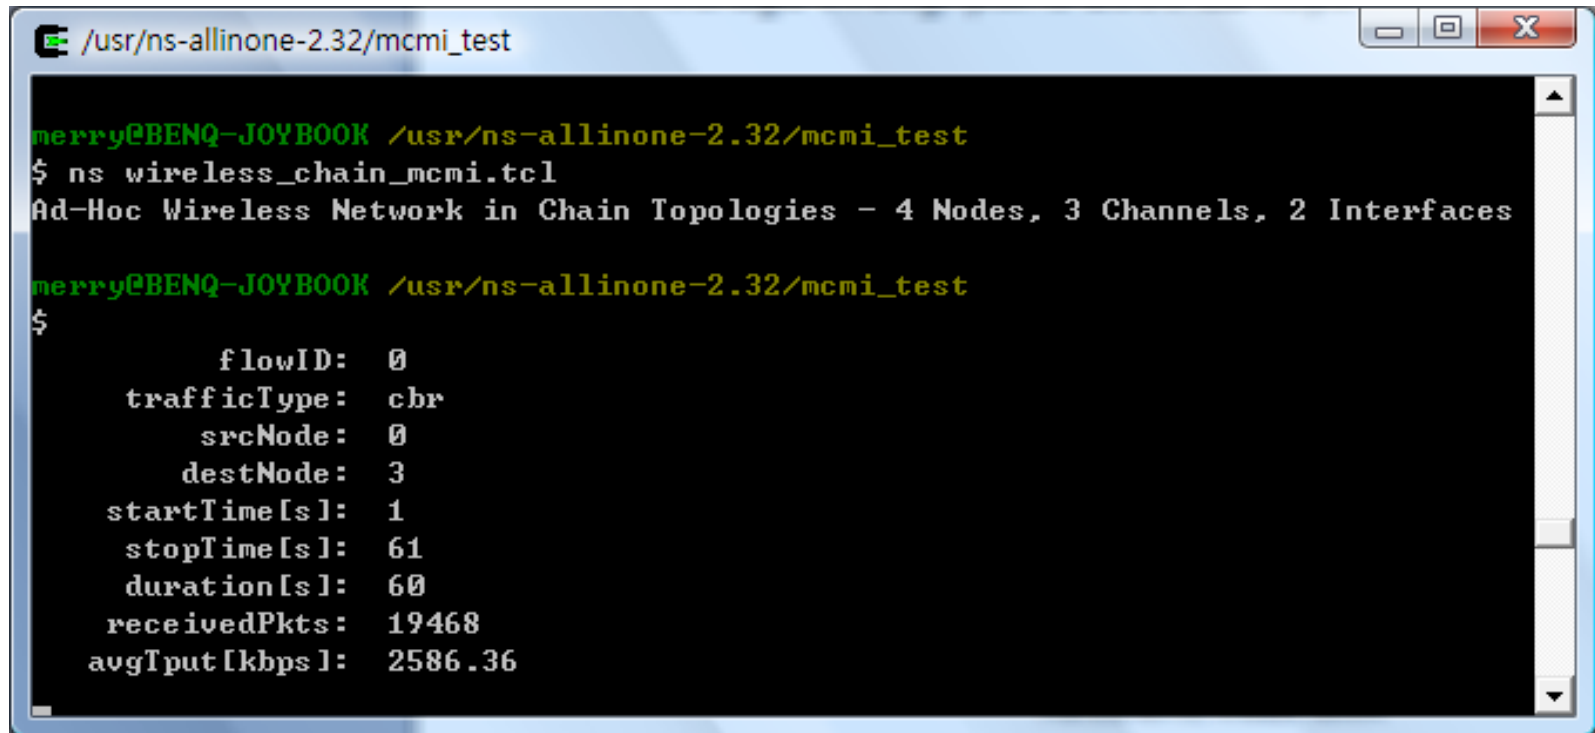

Simulation: Interface Switching

- Example: 4 nodes, 3 channels [0, 1, 2], 2 interfaces [0, 1]
- $NT[n]$ is the fixed channel used by node n
- $CUL[c]$ is the number of nodes using c as their fixed channel
- Fixed Channel (FC)
- Switchable Channel (SC)

Node 0	Node 1	Node 2	Node 3
NT[0] = 2 CUL[2] = 1	NT[1] = 0 CUL[0] = 1	NT[2] = 2 CUL[2] = 1	NT[3] = 1 CUL[1] = 1
FC = 2 SC = 0	FC = 0 SC = 2	FC = 2 SC = 0	FC = 1 SC = 2
	NT[0] = 2 NT[1] = 0 CUL[0] = 1 CUL[2] = 1	NT[1] = 0 NT[2] = 2 CUL[0] = 1 CUL[2] = 2	NT[2] = 2 NT[3] = 1 CUL[0] = 1 CUL[1] = 1 CUL[2] = 1
NT[0] = 2 NT[1] = 0 CUL[0] = 1 CUL[2] = 2	NT[0] = 2 NT[1] = 0 NT[2] = 2 CUL[0] = 1 CUL[1] = 1 CUL[2] = 2	NT[1] = 0 NT[2] = 2 NT[3] = 1 CUL[0] = 1 CUL[1] = 1 CUL[2] = 2	
FC = 2 but CUL[2] is large → FC = 1	NT[0] = 1 NT[1] = 0 NT[2] = 2 CUL[0] = 1 CUL[1] = 2 CUL[2] = 1	NT[1] = 0 NT[2] = 2 NT[3] = 1 CUL[0] = 1 CUL[1] = 1 CUL[2] = 1	NT[2] = 2 NT[3] = 1 CUL[0] = 1 CUL[1] = 1 CUL[2] = 1
NT[0] = 1 NT[1] = 0 CUL[0] = 1 CUL[1] = 1 CUL[2] = 1			
FC = 1 SC = 0	FC = 0 SC = 2	FC = 2 SC = 1	FC = 1 SC = 2

Simulation: Sample ns-2 Output

- 4 nodes, 3 Channels, 2 interfaces:
 - CBR traffic from Node 0 to Node 3
 - Average throughput is 2586.36 kbps

```

/usr/ns-allinone-2.32/mcmt_test

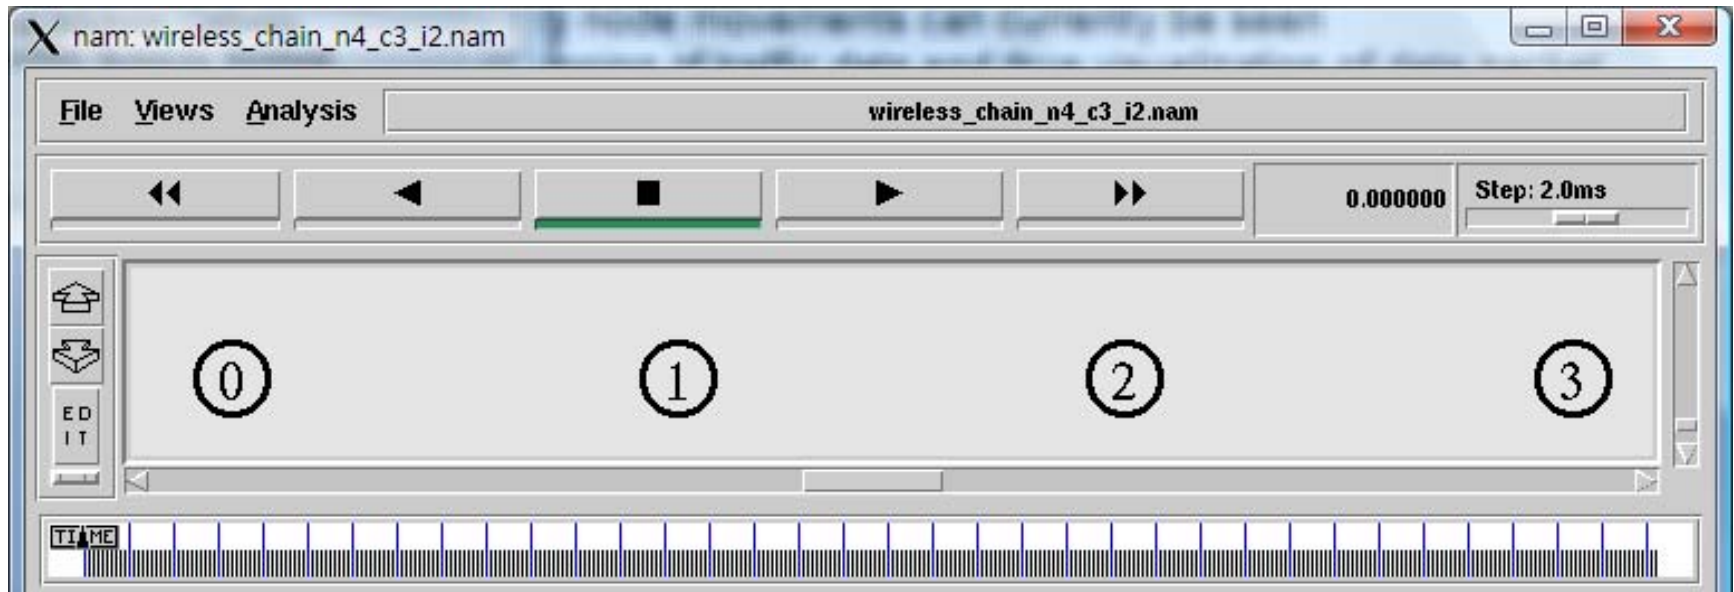

merry@BENQ-JOYBOOK /usr/ns-allinone-2.32/mcmt_test
$ ns wireless_chain_mcmt.tcl
Ad-Hoc Wireless Network in Chain Topologies - 4 Nodes, 3 Channels, 2 Interfaces

merry@BENQ-JOYBOOK /usr/ns-allinone-2.32/mcmt_test
$
    flowID: 0
    trafficType: cbr
    srcNode: 0
    destNode: 3
    startTime[s]: 1
    stopTime[s]: 61
    duration[s]: 60
    receivedPkts: 19468
    avgTput[kbps]: 2586.36

```

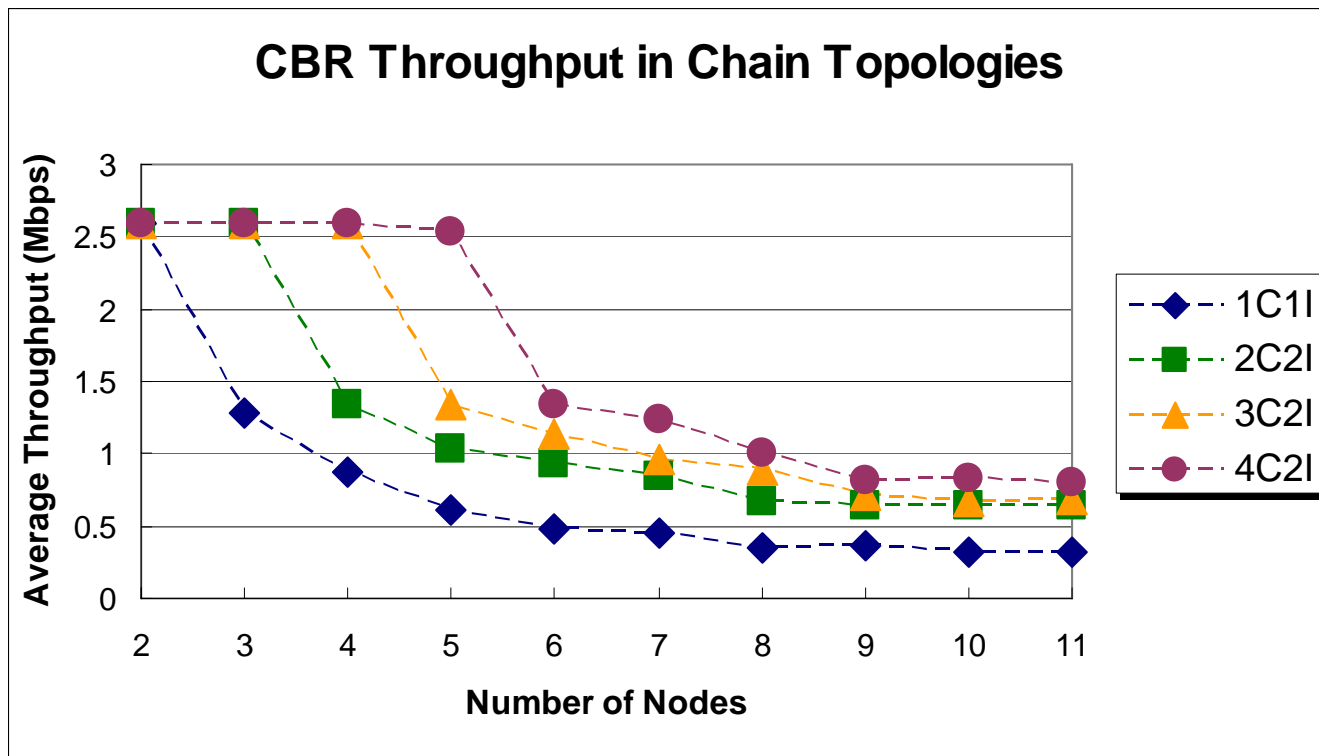

Simulation: Sample nam Output

- Network Animator (nam) in ns-2.32:
 - only nodes can currently be seen
 - dumping of traffic data and thus visualization of data packet movements for wireless scenarios is still not supported
- The following is a chain topology with 4 wireless nodes:

Simulation: Results

- Average throughputs while varying the number of channels, $n \rightarrow nC2I$ vs. $1C1I$

Simulation: Observations

- The throughput of 1C1I networks degrades as the number of nodes increases by 1 each time
 - intermediate nodes cannot send and receive data at the same time
 - interference within the carrier sense range
- Higher throughput with multiple channels and 2 interfaces on each node
 - **interface switching** assigns the fixed channel of successive nodes to different channels
 - intermediate nodes can send data to the next node using its switchable interface, while receiving data on its fixed interface
- Smaller throughput improvement when the number of nodes $>$ number of channels + 1
 - some nodes will be on some common channels \rightarrow interference
 - however, generally still higher than the case of 1C1I

Questions?

- Thank you!
